ALMA archive

Basics of Interferometry

Telescope resolution $\sim \lambda/D$
IRAM 30m $\sim 11''$ @ 1mm

To get higher resolution at mm wavelenghts
--> very large telescopes with very high surface accuracy

Technically difficult!

Aperture Synthesis Technique

- Replacing a single large telescope by a collection of small telescopes “filling” the large one
- Signal received by telescopes are combined by pairs
- Each antenna pair (**baseline**) measures a Fourier component of the source brightness distribution (**visibility**)
- Given sufficient number of measurements the source brightness distribution can be obtained by Fourier inversion

2-D Fourier Transform

$T(l,m)$

$V(u,v)$ amplitude

δ function

$\mathcal{F} \rightarrow$

constant

Narrow features

$\mathcal{F} \downarrow$

elliptical
Gaussian

$\mathcal{F} \rightarrow$

elliptical
Gaussian

Wide features

uniform
disk

$\mathcal{F} \rightarrow$

Bessel
function

Sharp edges

$\mathcal{F} \downarrow$

**High spatial
frequencies**

uv plane: Fourier transform space.
Each point on this space is related to the distance between each pair of antennas.

But we actually sample the Fourier domain at discrete points

$$V_{\text{meas}}(u,v) = S(u,v) V_{\text{ideal}}(u,v)$$

where $S(u,v)$ is the sampling function

$S = 1$ at points where visibilities are measured

and $S = 0$ elsewhere

Applying the convolution theorem:

$$\text{FT}(V_{\text{meas}}) = \text{FT}(S) * \text{FT}(V_{\text{ideal}})$$

The Fourier transform of the sampled visibilities gives the true sky brightness convolved with the Fourier transform of the sampling function (called **dirty beam**).

$$T^D(x, y) = D(x, y) \otimes T(x, y)$$

To get an image from interferometric data we need to Fourier transform sampled visibilities, and deconvolve for the dirty beam → **clean**

Earth rotation & Aperture Synthesis

- Possibility to measure different Fourier component without moving antennas
- Increasing the **uv plane coverage** improves images quality

Sampling in the uv plane

Associated image of a point source

Synthesis array is 'blind' to structures on angular scales both smaller and larger than the range of fringe spacings given by the antenna distribution.

FOV

$$FOV \propto \frac{\lambda}{D}$$

Resolution

$$\theta_{res} \propto \frac{\lambda}{b_{max}}$$

Maximum scale observable

$$\theta_{max} \propto \frac{\lambda}{b_{min}}$$

Sensitivity

$$\sigma \propto \frac{T_{sys}}{A_{eff} \sqrt{N(N-1)} \Delta \nu \tau}$$

T_{sys} System temperature

A_{eff} Effective area

N Number of Antennas

$\Delta \nu$ Bandwidth

τ Observing time

That's Why ALMA !

- Dry site (low pwv)
- low T_{sys}
- >6500sqm of effective area
- 1225 baselines for the main array
- Short spacings with ACA

Excellent instantaneous uv
coverage
& high sensitivity
< 0.05mJy @100 GHz in 1 hr

- Up to 16km baselines

subarcsec
resolution
40 mas @ 100 GHz,
5 mas @ 900 GHz

- 10 spectral bands
- 70 correlator modes

Flexibility in
spectral studies

ALMA full array capabilities

Antennas: 50 x 12m
+ 12 x 7m & 4 TP (ACA)

10 bands 84-950 GHz
(possible extension to ~ 30 GHz)

Total Bandwidth: 16 GHz
(dual pol, 2 GHz/ baseband)

Spectral resolution::
0.008 km/s @ 300 GHz

Baselines : 150 m – 16 km

Spatial resolution: ~ 0.2" @ 300 GHz x 1km baseline

Polarization: full Stokes parameters

ALMA science drivers

Detect spectral line emission from C⁺ in a normal galaxy like the Milky Way at $z=3$ in less than 24 hrs

Image the gas kinematics in protostars and proto-planetary disks around young Sun-like stars in the nearest molecular clouds (at 150 pc)

Provide precise high dynamic range (~ 1000) images at an angular resolution of 0.1 arcsec.

ALMA Proposal categories

Cosmology and the high redshift universe

Galaxies and galactic nuclei

ISM, star formation and astrochemistry

Circumstellar disks, exoplanets and the solar system

Stellar evolution and the Sun

Cosmology and high redshift Universe

- **Negative K- correction**
- **Flux is z independent in mm and sub mm**

Cosmology and high redshift Universe

- Galaxies at high redshift

Cosmology and high redshift Universe

- **Cycle0 results:** Hodge et al. 2013; Karim et al. 2013; Simpson et al. 2013, Swinbank et al. 2014 and many other papers

Follow-up of LABOCA LESS survey: 122 submm sources.
ALMA Band7 observations reveal that ~35% of the LABOCA sources are resolved in multiple SMGs.
Serendipitous detections of bright emission lines in two SMGs which are likely CII emission @ $z \sim 4.4$.

Cosmology and high redshift Universe

- **Cycle0 results:** Vieira et al. 2013; Weiss et al. 2013; Hesaveh et al. 2013

NIR Images + ALMA (Band 7) 870 μm Contours

ALMA Band3 and Band7 observations of strongly gravitationally lensed sources.

Cosmology and high redshift Universe

- **Cycle0 results:** Vieira et al. 2013; Weiss et al. 2013; Hesaveh et al. 2013

ALMA Band 3 first spectroscopic redshift survey

In some cases unambiguous z determination from ALMA only.

Cosmology and high redshift Universe

ALMA long baselines
(up to 15 km) campaign

the number of papers
shows how ALMA will enable
astronomers to make more
discoveries in the years to
come

Cosmology and high redshift Universe

- **ALMA deep field in SSA22: concentration of dusty starbursts in a $z=3.09$ protocluster core**

ASTE observations
there might be a
cluster of monstrous
galaxies

ALMA observations
nine monstrous
galaxies can be
identified

Subaru observations
not all the galaxies are
visible.

Cosmology and high redshift Universe

- **ALMA deep field in SSA22: concentration of dusty starbursts in a $z=3.09$ protocluster core**

The shape of the cluster indicates the presence of a huge 3D web of invisible dark matter. Monstrous galaxies seem to be located in the intersections of dark matter filaments.

Umehata et al. 2015

Cosmology and high redshift Universe

- The assembly of “normal” galaxies at $z \sim 7$ probed by **ALMA**

Detection of the CII emission at $z=7.107$ but spatially offset from the optical emission. This suggests that molecular clouds in the central parts of primordial galaxies are rapidly disrupted by stellar feedback.

Maiolino et al. 2015

Galaxies and galactic nuclei

Star forming clouds have been identified in the closeby starburst galaxy NGC253 in different molecular emissions.

These clouds are much more massive, ten times denser, and far more turbulent than similar clouds in the Milky Way.

NGC253
Leroy et al., 2015

Galaxies and galactic nuclei

The distribution around the AGN of a variety of molecules has been revealed.

Unexpected molecules (HC_3N and CH_3CN) have been detected in the circumnuclear disk.

HL Tau star
as seen by CARMA.

CARMA observations : $0.17'' \times 0.13'' \sim 18$ AU
Kwon et al. 2011

Circumstellar disks....

Long baselines (15 km) science verification

ALMA observations of HL Tau reveal substructures within the disc that have never been seen before and even show the possible positions of planets forming.

Resolution to see a penny from ~100 km!

ALMA observations : 0.035"
Partnership ALMA, 2015

Circumstellar disks....

The dust surrounding the star HD 107146, a younger version of our Sun, is thicker in the outer reaches of the disk, and thinner in the inner regions. This suggests that Pluto-size planetesimals cause smaller grains to smash together.

The dark ring-like structure in the middle may indicate a gap where a planet is sweeping its orbit clear of dust.

1.25 mm continuum, res=1".15x0".84

HD 107146

Ricci et al., 2015

Circumstellar disks....

Broad elliptical ring around the double star. The disk begins about 50 times the Sun-Hearth distance.

Most of it consists of gases (^{13}CO and C^{18}O , green and blue), but there is a noticeable arc free of gas (red). In this arc the temperature is so low that the gas turns into ice and sticks to the grains.

This process is thought to act as a strong catalyst for the formation of planetesimals, and planets.

10	787 – 950	0.3 – 0.4	7.8 – 6.5	3.44

ALMA Cycle 4

Non standard observing modes

Cycle 4 includes

- ★ **standard** modes: those already used in previous cycles, and for which the data can be reduced by the pipeline
- ★ **non-standard** observing modes
are less well characterized and the data need to be processed manually by ALMA staff. Up to **20%** of the total observing time will be assigned to such projects.
 - ★ Bands 8,9, and 10
 - ★ Band 7 Long baselines (>2.7 km)
 - ★ Polarization
 - ★ Spectral Scan
 - ★ Solar observations
 - ★ VLBI observations
 - ★ Non standard calibrations

ALMA Cycle 4

Large programs

Cycle 4 includes

- ★ > 50 hours with the 12-m array or ACA stand-alone or both if needed for short spacing
- ★ Only standard observing modes
- ★ Proposal format different from regular proposals
- ★ In addition to PI and co-I, any number of co-PIs can be designated
- ★ 15% of the time will be allocated to Large Programs (~450 hrs for 12 m array and 270 for ACA stand-alone)

Cycle 3 Call for Proposals

The [Cycle 3 Call for Proposals](#) is now open for scientific observations that will be scheduled from October 2015 to September 2016. The proposal submission deadline is 15:00 UT on April 23, 2015.

This is the website for **The ALMA Science Portal**, served from one of the **ALMA Regional Centers (ARCs)** of the ALMA partner organizations: ESO, NRAO or NAOJ. You may switch between the different instances of the portal through the links to the appropriate ALMA partner at the top banner. Through this portal you can find details about the technical capabilities of ALMA, how to propose for observing time, and how to access ALMA data. It includes links to all official ALMA documents and tools, including those for preparing and submitting proposals and processing ALMA data. In order to access some of the

Proposal preparation

★ The observing tool (OT) is a Java application used for the preparation and submission of ALMA proposals, and for phase II materials.

Proposal preparation

★ The OT to be used for cycle 4 observations will be released with the call for proposals.

It includes a sensitivity calculator and viewers to assist with correlator setup and mapping parameters

For details on the OT:

★ Observing tool documentation is available

★ You can ask questions through the helpdesk

Proposal preparation

fundamental observational parameters

ALMA is a very flexible instrument, data can be obtained over a wide range of observational parameters, which must be defined and justified in the proposal. Careful choices are required to ensure that the project's scientific aim can be met.

★ Angular resolution and maximum recoverable scale

Due to the nature of interferometers only a discrete set of angular scales is observed. Consider that some emission can be filtered out in a given baseline distribution.

$$\theta_{res} \propto \frac{\lambda}{b_{max}}$$

$$\theta_{max} \propto \frac{\lambda}{b_{min}}$$

Proposal preparation fundamental observational parameters

★ Field of view

To get images larger than the interferometer FOV with flat sensitivity, observations can be obtained observing in series many adjacent locations on the sky. Mosaics can be costly in terms of observing time.

The OT spatial visualizer allows to define pointings and mosaic regions

$$FOV \propto \frac{\lambda}{D}$$

Proposal preparation fundamental observational parameters

★ Spectral resolution

minimum separation in frequency whereby adjacent independent features can be distinguished.

For continuum observations or very broad spectral lines, wide bandwidths and low spectral resolution are used. Maximum bandwidth: 7.5 GHz.

For spectral lines, narrower bandwidths with higher spectral resolution channels may be required. Sensitivity will decrease.

A combination of high and low resolution spw can be chosen.

$$\sigma \propto \frac{T_{\text{sys}}}{A_{\text{eff}} \sqrt{N(N-1) \Delta \nu \tau}}$$

★ The OT spectral viewer helps in setting the spectral choices.

Proposal preparation fundamental observational parameters

★ Sensitivity

<https://almascience.eso.org/proposing/sensitivity-calculator>

$$\sigma \propto \frac{T_{\text{sys}}}{A_{\text{eff}} \sqrt{N(N-1) \Delta \nu \tau}}$$

ALMA proposals ask for sensitivity not observing time. Ideally S/N ~ 5, S/N < 3 must be fully justified

The screenshot shows the ALMA Sensitivity Calculator interface. It is divided into two main sections: 'Common Parameters' and 'Individual Parameters'.

Common Parameters:

- Dec: 00:00:00.000
- Polarization: Dual
- Observing Frequency: 345.0 GHz
- Bandwidth per Polarization: 7.5 GHz
- Water Vapour Column Density: 0.913mm (3rd Octile)
- tau/Tsky: tau0=0.158, Tsky=39.538
- Tsys: 157.027 K

Individual Parameters:

	12m Array	7m Array	Total Power Array
Number of Antennas	36	10	2
Resolution	1.0 arcsec	5.97455393852278	17.923661815568337
Sensitivity (rms)	0.00000 uJy	0.00000 uJy	0.00000 uJy
(equivalent to)	0.00000 K	0.00000 K	0.00000 K
Integration Time	60.0 s	60.0 s	60.0 s

Integration Time Unit Option: Automatic

Sensitivity Unit Option: Automatic

Buttons: Calculate Integration Time, Calculate Sensitivity

Some a priori knowledge of source size and emission distribution are important when estimating the required sensitivity of an ALMA observation starting from previous measures.

A source bright in 30" beam, maybe difficult to detect in a 1" beam if the emission is spread over a few arcseconds. If smoothly spread over 30" it may have a flux density only $(1/30)^2$ as bright.

Proposal preparation

ALMA simulation tools

In planning observations of complex fields uv-coverage can be as important to consider as sensitivity. Having a reasonable model for the source structure simulations of ALMA observations can be done.

★ **CASA (Common Astronomy Software Application)**
tasks simalma, simobserve, simanalyze

★ **Observation Support tool**
web-based interface
Less control on the simulation and imaging process than simalma

In both noise values determined can be different from those calculated with the exposure calculator, and **should not be used in the proposal**

Bandwidth	0.032 GHz
Track length	3 hours x 1.0 visits
System temperature	$T_{\text{sys}} = T_{\text{rec}} + T_{\text{sky}} = 37.0 + 4.42 = 44.15 \text{ K}$
PWV	0.5 mm
Theoretical RMS noise	0.000103323597098 Jy (in naturally-weighted map)
Restoring beam (resolution)	Major axis = 6.229 arcsec, minor axis = 5.176 arcsec, PA = 55.607 deg

ALMA Archive

A high level principle of ALMA is that identical data should not be taken twice unless scientifically necessary.

Duplication criteria are given in the Call for Proposal.

★ Check the ALMA archive

 ⚙

Source name (Sesame)
Source name to be resolved with Sesame.

Description
We use the external resolver Sesame to obtain coordinates for the source. Sesame queries the Simbad, NED and VizieR services.

Example
M87
NGC3375

Source
R Scl

Coordinates (RA Dec)
01:26:58.07 -32:32:36.6

Object type
!V* (Galactic variable star)

Resolver
Sesame using NED

**To get help during proposal preparation
or archival data reduction
you can contact us:**

help-desk@alma.inaf.it

**or book a face-to-face visit @:
Istituto di Radioastronomia Bologna**

**or contact me:
paladino@ira.inaf.it**

Summary

ALMA has already obtained unexpected scientific results

In Cycle 4 ALMA capabilities will furtherly improve

Proposal preparation tools available

Many public data are already available trough the ALMA archive

Grazie

Cosmology and the high redshift universe

Galaxies and galactic nuclei

ISM, star formation and astrochemistry

Circumstellar disks, exoplanets and the so

Stellar evolution and the Sun
